Abstract

Music Information Retrieval (MIR) is an interdisciplinary science of extracting non trivial information and statistics from music data sources. In today's digital age, music is stored in a variety of digitized formats - e.g midi, musicxml, mp3, digitized sheet music etc. Music Information Retrieval Software aim at extracting features from one or more of these source. MIR research helps in solving problems like automatic music classification, recommendation engine design etc. Users can then query the acquired statistics to acquire relevant information.

The author proposes and implements a new Music Information Retrieval and Query Engine called Modulo7. Unlike other MIR software which deal with low level audio features, Modulo7 operates on the principles of music theory and a symbolic representation of music. Modulo7 is a full stack deployment, with server components that parse various sources of music data into its own efficient internal representation and a client component that allows consumers to query the system with sql like queries which satisfies certain music theory criteria (and as a consequence Modulo7 has a

ABSTRACT

custom relational algebra with its basic building blocks based on music theory).

Secondary Reader: Dr Yanif Ahmad

Acknowledgments

I would like to thank Dr David Yarowsky for giving me the opportunity to work on this project. His detailed insights have immensely helped me to power through my work. I would like to thank Dr Yanif Ahmad for his crucial help in the systems aspects of my query engine and the implementation of the server side components.

Dedication

This thesis is dedicated to my family and to all the music lovers in the world.

Chapter 1

Introduction

Why does a person like a particular song? What are the inherent aspects of a song that pleases a person's musical taste? Is it the complexity of a song, the beat the song or just a particular melodic pattern ? More so if a person likes a song, can we predict if he/she will like a similar song?

Music has been created since the dawn of civilization and these questions have plagued mankind just as long. In response to this, man has created elaborate systems of formal study for music and classification techniques in almost every ethnic community since antiquity. Two notable examples are the western system of solfege and classical music theory and the Indian system of raagas. These elaborate systems are based on very simple fundamental building blocks of melody and harmony and simple rules that govern the interplay of these building blocks. However very complex pieces of

CHAPTER 1. INTRODUCTION

music can be created with these simple rules depending on the skill and virtuosity of artists. Composers use these rules and concepts to create novel music for mass consumption.

In the modern era industry and academia have attempted to address the problem of music recommendation and music classification. The industry has predominantly favored approaches that look at user preferences and history. For example Amazon Music recommendation works on users shopping history. Pandora on the other hand hires an army of musicologists to ascertain how a song is similar to another song and creates software that leverages this adhoc generated data. These approaches are either expensive in the human labor needed or in the amount of data processed that is input from a large number of users. More recently, companies like Echo Nest has extensively extracted features from music sources and mined cultural information on the web but leave it at consumers how best to leverage the data. Hence symbolic MIR is not traditionally used in industry and music theory is an after thought.

Academia on the other hand attempts to solve very particular problems in MIR. Typical examples would be cover song detection, processing information via signal processing, audio feature extraction, optical music recognition etc. In most cases the applications are of a very specific domain and does not fully scale with bulk music data. Generic frameworks like the jMIR (which also happens to be a major inspi-

CHAPTER 1. INTRODUCTION

ration for modulo7) suite for automatic music classification exists, which is meant to facilitate research in MIR with a machine learning focus. However academia is disconnected with industry and no full scale MIR engines can satisfy the scale of industry applications.

This work is attempt to bridge both communities. Modulo7 is a full stack deployment, providing both a server architecture and a sql like client to query based on music theory criteria.

Chapter 2

Server side architecture

Modulo7 is designed with the purpose of scalability. A block diagram of the components of the server side architecture is presented below :-

1. Source Converter : Converts music sources (e.g. music XML, midi etc) into modulo7's binary representation.
2. Music Theory Models : The model is a description of music theoretic criteria that can be applied on top of song. Examples would be melodic contour, tonal histogram etc.
3. Distributed Storage Mechanism : The modulo7 internal representation is
